

How 4orm Works

A plain-language guide to what we are building, written so you can explain it with confidence. The technical detail is underneath each part, set apart, for when you want it.

THE ONE-
SENTENCE
VERSION

What 4orm is

4orm is Canada's neutral, regulated settlement layer for tokenized real-world assets. In plain terms: we are the layer that makes a transfer of a valuable asset final and legal across two institutions, in Canadian dollars.

Here is the problem we solve. When a tokenized asset moves from one institution to another, it cannot become final and legal today. A stablecoin can move on a chain, but it cannot be cleanly handed from one regulated institution to another and recognized there. Real-world assets like real estate, receivables, and equipment cannot move easily at all. Every institution's tokenized money and assets sit on separate, single-bank systems. There is no neutral Canadian-dollar place where a tokenized deposit and a tokenized asset can settle against each other.

The token itself is not the hard part. The hard part is making the transfer final, legal, and recognized on the other side. That is the whole company. Own the record of title, the cash leg, and the rules, and you can settle almost anything.

FOR THE TECHNICALLY CURIOUS

The category term is core financial market infrastructure: a regulated control plane, not a crypto exchange. The platform is chain-agnostic and bank-integrated, and it speaks ISO 20022, the messaging standard the banks already run. The regulated pieces (the compliance perimeter, the ledger of record, the token registry, and the banking integration) live inside our boundary; the blockchain underneath is swappable, which is deliberate.

2.0

THE
THREE
LEGS

Three things travel with any transfer

For a transfer to be final across two institutions, three things have to move together. 4orm moves all three in one settlement. This is the mental model to keep; everything else is detail hanging off it.

Title

The authoritative record of who owns the asset. 4orm keeps the master record and the registry of the tokens, so ownership changes hands cleanly and is recognized on the other side.

The cash leg

The money side of the trade. It settles at the same moment the asset moves, so neither institution is left exposed. The cash is a tokenized bank deposit, issued and held by a regulated bank as the bank's own money. 4orm connects to it. 4orm does not issue it and does not hold anyone's money.

The rules

Identity, eligibility, sanctions, and jurisdiction travel with the asset, so a transfer that should not be allowed simply cannot complete. Compliance is built into the movement, not bolted on afterward.

Why the cash leg is the wedge

Every settlement has a cash leg; you cannot swap an asset without money on the other side. A tokenized bank deposit is that cash leg, in regulated Canadian dollars institutions already trust. Own the cash leg and 4orm becomes the settlement asset every other transfer needs, from bonds to receivables to real estate.

FOR THE TECHNICALLY CURIOUS

Title is the ledger of record plus a token registry that binds each token to its legal and economic claim. The cash leg is a bank-issued deposit token that stays the bank's liability on the bank's balance sheet, which is why 4orm needs no banking licence. The rules are a policy-as-code compliance perimeter: identity, accreditation, and sanctions checks run as executable, auditable logic at the moment of transfer.

3.0

UNDER
THE
HOOD

The stack, in five layers

You do not need this to explain 4orm, but it helps to have seen it. The platform is organized as five layers, each with one job. The design was reviewed independently and scored 7.5 out of 10 on architecture fit and 8.5 on strategic fit before a single line of production code was written.

LAYER	WHAT IT DOES	IN PLAIN TERMS
1. Permissioned ledger	Records settlements, tokenized deposits, and asset transactions.	The authoritative book of record.
2. Identity and access	Manages institutional identities, roles, and permissions.	Who is allowed to do what.
3. Asset registry	Binds each token to its legal and economic claim.	The token actually means something.
4. Settlement orchestration	Coordinates the payment, the delivery-versus-payment, and treasury flows.	Makes both legs move together.
5. Integration	Connects to core banking, custody, and reporting systems.	Plugs into what banks already run.

The phrase we use internally is "boring on purpose." Every technology choice favors auditability, control, and compliance over anything experimental. That is the point. Institutions do not adopt clever; they adopt dependable.

FOR THE TECHNICALLY CURIOUS

Permissioned means every participant on the ledger is a known, vetted institution, not an anonymous public-chain address. Security posture: SOC 2 Type I in the pilot phase and Type II before scaled deployment, independent penetration testing at each major release, and hardware security modules with multi-party computation protecting keys. High-availability deployment with defined disaster-recovery targets.

4.0

HOW A
TRANSFER
MOVES

Watch one transfer go through

Here is the whole thing in motion, from Institution A to Institution B, the way it will run in the pilot. Read it once and the product clicks.

STEP WHAT HAPPENS

- 1 Institution A signs and sends an instruction to move an asset to Institution B.
- 2 4orm checks the rules: identity, eligibility, sanctions, jurisdiction. If any fail, it stops here.
- 3 4orm registers the token and writes the movement into the ledger of record.
- 4 The asset leg and the cash leg are settled together, delivery-versus-payment, so neither side is exposed.
- 5 The transfer reaches a single, authoritative point of finality: the law now treats it as done.
- 6 4orm produces a complete evidence and reconciliation record for both institutions, counsel, and the regulator.

The asset changes hands once, cleanly, under supervision. Both legs move together, and the moment it commits it is final.

THE SENTENCE TO LEAD WITH

FOR THE TECHNICALLY CURIOUS

The instruction is signed and idempotent, with a correlation ID, so it can never be double-applied. The ledger is append-only; every state change is bound to its authorization, route, acknowledgement, and finality record. Finality is a legal status under the Payment Clearing and Settlement Act and the international CPMI-IOSCO principles, not a speed measurement, which is why we say settlement finality and never "atomic settlement."

5.0

WHAT WE
ARE, AND
ARE NOT

The boundary, so you can answer cleanly

An experienced advisor will get asked where 4orm stops. The line is deliberate and easy to hold. We issue the record of title and operate the rules. We do not touch the money or the assets themselves.

We are

SOFTWARE, THE RECORD OF TITLE, AND THE COMPLIANCE RULES. THE NEUTRAL SETTLEMENT LAYER.

We are not

A BANK, A DEPOSIT-TAKER, A CUSTODIAN, A STABLECOIN ISSUER, OR THE AML OFFICER OF RECORD.

The bank issues and holds the deposit as its own money. A licensed custodian holds the assets. The regulated institutions keep their own obligations. 4orm provides the software and the record of title, and stays neutral so a rival bank or a credit union will settle through it, which they will never do through a competitor's platform. All of this is subject to the required regulatory approvals.

FOR THE TECHNICALLY CURIOUS

This boundary is what keeps 4orm out of deposit-taking and custody regulation. Because the blockchain layer is swappable and the regulated functions sit inside our perimeter, 4orm is not betting the company on any one chain or any one bank. Neutrality is a design constraint, not a slogan.

6.0
WHERE
IT
GOES

Built narrow now, neutral network later

We build one narrow thing perfectly first, and the architecture is deliberately general so the later phases are configuration, not reinvention. The first release is a read-only sandbox running on synthetic data: a supervised signal with no live money, no custody, and no token issuance. It proves the rail safely, then hardens toward a real institutional pilot.

Phase 1	Phase 2	Phase 3+
THE CASH LEG. STAND UP THE TOKENIZED BANK DEPOSIT AS THE SETTLING MONEY.	SETTLE A SECOND TOKENIZED ASSET AGAINST THAT CASH LEG. TWO ASSETS, ONE FINAL SETTLEMENT.	CONDITIONAL SETTLEMENT, THEN AN OPEN NETWORK OTHER ISSUERS PLUG INTO.

Why this is hard to copy

The direction is already proven abroad by the UK Regulated Liability Network and Fnality, and at home by the Bank of Canada's Project Samara. None of them is building the neutral, bank-integrated, Canadian-dollar layer that connects them. JPMorgan's Kinexys proves the demand but is single-bank and US-dollar-first; a rival will not settle title through a competitor. The real contest for the neutral Canadian-dollar quadrant is the domestic incumbent, TMX and CDS. That gap is the opportunity, and it is ours to take.

This brief is an onboarding summary for 4orm advisors. It draws on materials held in full in the 4orm data room and does not constitute an offer to sell securities. Figures and positioning are current as of July 2026; where this summary and the source documents differ, the source documents govern.
